

Finz Internship Challenge

Accounting Data Pipeline, QuickBooks Integration, and P&L Reconciliation

1. Overview

Finz is building AI-native operating finance for real economy businesses. This challenge tests your ability to build a reliable financial data pipeline, integrate with QuickBooks Online, and validate the accounting output. Complete the challenge over the weekend.

You may use Claude Code, Codex, Cursor, ChatGPT, Gemini, or other AI development tools.

2. Objective

Build a working application that accepts raw bank transaction data, normalizes and classifies each transaction, generates a cash-basis Profit and Loss statement, syncs approved transactions to a QuickBooks Online sandbox, and reconciles the application's P&L against the P&L produced by QuickBooks.

3. Challenge Dataset

The workbook below contains the company setup, the required QuickBooks chart of accounts, and raw bank transactions covering Apr 1, 2026 through Jun 30, 2026 .

<https://docs.google.com/spreadsheets/d/1irWmKZycuDMDMg6LBCHKqo7ksU2eUzCfXMsMeuePJM/edit>

Notes:

- A. Treat the data as untrusted. Preserve the original values before normalization.
- B. Do not alter the supplied source data or manually add classifications to it.

4. Your Task

4.1 Set Up QuickBooks Online

- Create an Intuit developer account and a QuickBooks Online sandbox company.
- Configure the company using the Company Setup tab in the dataset.
- Create the chart of accounts provided in the QBO Chart of Accounts tab.
- Document any setup choices or QBO detail-type differences.

4.2 Build the Data Ingestion and Normalization Pipeline

- Build a simple interface that uploads the supplied bank data.

- Design the upload flow so it can support other common bank CSV or Excel exports through configurable column mapping. Do not hard-code the application to one column order.
- Preserve the raw source record and create a normalized transaction record.
- Normalize dates, amounts, currency, bank accounts, and transaction descriptions.
- Detect duplicate transactions, including duplicates created by overlapping source files.
- Flag records that cannot be processed safely instead of silently dropping them.

4.3 Classify and Review Transactions

- Assign each transaction a transaction type, counterparty, and QuickBooks account.
- Correctly distinguish revenue, Cost of Goods Sold, operating expenses, refunds, transfers, owner activity, and fixed-asset purchases.
- Provide a clear explanation or confidence indicator for each classification.
- Allow the user to review and correct classifications before syncing to QuickBooks.
- Store approved corrections so repeated transaction patterns can be classified consistently.

4.4 Generate the Internal P&L

- Generate cash-basis P&L statements for each month and for the full three-month period.
- Show revenue, Cost of Goods Sold, gross profit, operating expenses, and net profit or loss.
- Show account-level totals and allow the user to view the transactions behind each P&L line.
- Exclude transfers, owner activity, duplicate transactions, and fixed-asset purchases from the P&L.

4.5 Sync Approved Transactions to QuickBooks Online

- Sync only reviewed or safely classified transactions.
- Map every transaction to a valid account in the sandbox chart of accounts.
- Prevent duplicate posting when the sync is run more than once.
- Store the QuickBooks transaction ID and sync status for every posted transaction.
- Handle API failures clearly and allow failed transactions to be retried safely.
- You may choose the appropriate QuickBooks transaction types, but explain your accounting and integration decisions.

4.6 Reconcile the P&L

- Pull the cash-basis Profit and Loss report from QuickBooks through the API.
- Compare the application's P&L with the QuickBooks P&L for each month and for the full period.
- Reconcile every account and net profit or loss.

- Show the application amount, QuickBooks amount, difference, reconciliation status, and explanation for any mismatch.
- A successful API sync is not sufficient. The accounting output must reconcile.

5. Required Interface

Your application should provide the following minimum workflow:

- Upload and map raw bank data.
- Review normalized and classified transactions.
- Correct classifications before sync.
- View monthly and consolidated P&L statements.
- Sync approved transactions to QuickBooks.
- View the QuickBooks reconciliation result.

6. Technical Requirements

Build the application using Python, FastAPI, MongoDB, Gemini, and the QuickBooks Online API. You may choose the frontend framework and supporting libraries.

AI coding tools are allowed, but you are responsible for validating the implementation and accounting results.

7. Deliverables

- Source-code repository.
- Working application and setup instructions.
- README covering architecture, data model, classification approach, QuickBooks integration, duplicate prevention, assumptions, and known limitations.
- Internally generated monthly and three-month P&L statements.
- QuickBooks P&L reports and the completed reconciliation output.
- A short screen recording showing the complete flow from raw-data upload through QuickBooks reconciliation.
- A brief AI usage note describing the tools used, what they generated, and what you independently validated.

8. Submission

Submission deadline: Jul 27, 2026
